

Primary protein-changing candidates: time-localized usage shifts

Cell value = mean usage change

* global Benjamini-Hochberg $q \leq 0.05$ across all transcript $\times$ time tests

Input: within-gene TPM usage from 12 Salmon samples and global-BH adjusted DRIMSeq time contrasts. Red indicates increased usage, blue decreased usage, and a star marks $q \leq 0.05$. RNA-level evidence does not establish protein isoform production.
